---

---

---

---

## Process

- A process is a conceptual structure of "work" on a CPU.
- The work performed by a process is a task.
  - A process and task are synonymous in Linux.

2

---

---

---

---

---

---

---

---

## Process Control Block (PCB)

- Information needed to identify one process from another.
  - Process ID (PID)
  - Copy of the registers
  - Heap memory allocations
  - Page map
  - File allocations (descriptors)
  - Device buffers
- Scheduling information
  - Runtime
  - Context switches

3

---

---

---

---

---

---

---

---

## Process Creation

- Created by the OS from a system call
  - Linux: `fork()`, `exec*()`
  - Windows: `CreateProcess()`
- A created process must be loaded into memory (at least what is necessary to run).
  - CPU can only fetch instructions from memory.

---

---

---

## Process Execution

- Operating System's Duties
  - Restore register's state
  - Reprogram MMU
  - Restore driver contexts
  - Set program counter (instruction pointer) to last known instruction to execute.
  - Execute...

## Process States

- A process may be running, waiting, put in the penalty box, etc.
- No standard "states"
  - Linux
    - `RUNNING`
    - `INTERRUPTIBLE SLEEP`
    - `UNINTERRUPTIBLE SLEEP`
  - Academic
    - `NEW`
    - `RUNNING`
    - `READY`
    - `BLOCKED`
    - `SUSPENDED`
    - `TERMINATED`

## Parent / Child Relationships

- Reporting system
- A parent can have many children
- A child can have one parent
  - When child dies, parent is notified (SIGCHLD for SYS-V).
- Child memory management
  - A child contains the parent's memory map until the child writes to it.
  - After the child's first write, the memory is copied, and the child has its own copy.

---

## PCB Organization

- PCBs are typically in a static array or dynamic list.
  - Dynamic lists require the OS to implement the heap.
    - This is NOT always expected!
- Linked lists
  - Save Memory
  - Allocation Overhead
- Static array
  - Fixed size at compile time
  - Wastes memory not being actively used

## PCB Wait vs Ready Queues

- Wait queue
  - Contains pointers that point to all processes waiting on I/O, or are sleeping for a period of time.
- Ready queue
  - Contains pointers that point to all processes waiting on the CPU.

## Threads

- Heavyweight vs Lightweight Threads
  - Heavyweight threads are new processes that detach from the parent.
    - Contain their own state, memory, etc.
  - Lightweight threads are tied to their parents.
    - Contain parent's memory, state, etc.
      - Saves on the time and memory used to create and execute a new process.

## Thread Control Blocks

- Contain only the information different from the thread's parent.
- Threads can turn into processes
  - Linux does this when a thread writes to memory.
    - MMU makes child's memory read-only
    - When child writes, it causes a page fault
    - OS handles this and duplicates memory
    - OS resumes thread as a new process
